Question 1 (50 points): Education

A school counselor was curious about the average of IQ of the students in her school and took a random sample of 25 students' IQ scores. The following is the data set:

```
y \leftarrow c(105, 69, 86, 100, 82, 111, 104, 110, 87, 108, 87, 90, 94, 113, 112, 98, 80, 97, 95, 111, 114, 89, 95, 126, 98)
```

1. Find a 90% confidence interval for the average student IQ in the school.

Using the code below I found the mean and standard deviation of the sample, and then calcuated the estimated standard error. We know that the population distribution of IQ scores will be normal. Since the sample size is small, we can assume the distribution of sample means will be a t-distribution, with n-1 = 24 degress of freedom. This will give us a wider margin of error compared to a using normal curve, which compensates for the uncertainty due to the small sample size. The code returns the appropriate t-score, which tells us that 90% of sample means of size 25 will lie within 1.71 standard errors of the sample mean. (I checked this against stats table also for my own understanding.) This gives a 90% confidence interval for the average IQ in the school of 94-103.

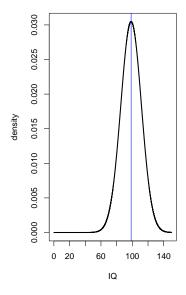

R has a built-in fuction that will generate a 95% confidence interval. Since it's such short code (below) I have run that also as a sense check, and I can confirm that my 90% CI fits within in.

```
t \cdot test(y)
```

Next, the school counselor was curious whether the average student IQ in her school is higher than the average IQ score (100) among all the schools in the country.

Before we conduct a hypothesis test (see next page), we can say straight away from the 90% CI interval that this sample has not provided evidence that the average IQ score in the school is above the national average. I have plotted the probability density of the sample means (code below), including a blue vertical line indicating the sample mean. We can see that the sample means would be spread both above and below 100, so we would not be surprised either way.

Probability density for sample means

Using the same sample, conduct the appropriate hypothesis test with $\alpha = 0.05$.

Null hypothesis: Average IQ in the school is less than or equal to 100; alternative hypothesis: average IQ in the school is greater than 100. The code below calculates the probability that the average IQ in the school is less than or equal to 100. The test statistic is the standardised variance from the sample mean to 100. The test assumes a t-distribution with 24 degrees of freedom. The p-value returned is 0.722. Since the p-value is larger than 0.05 we have no evidence to reject the null hypothesis, as expected from the discussion above. Means of sample size 25 from the school would be expected to be at or below the national average with a probability of 72%. A 72:28 split is not going to result in surprise either way.

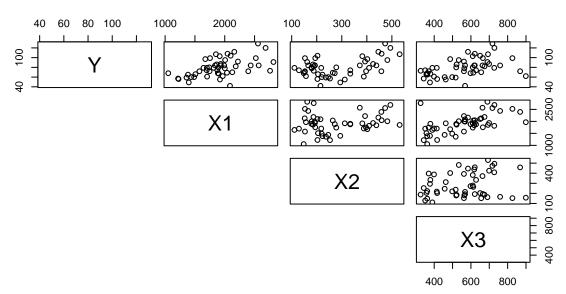

```
\begin{array}{lll} \text{1 test\_stat} & <- \text{ } (\text{mean\_y} - 100) / \text{se\_y} \\ \text{2 } P\_\text{value} & <- \text{ pt} (\text{abs}(\text{test\_stat}) \text{, } 24 \text{, lower.tail} = \text{TRUE}) \end{array}
```

Question 2 (50 points): Political Economy

Explore the expenditure data set and import data into R.

• Please plot the relationships among Y, X1, X2, and X3? What are the correlations among them (you just need to describe the graph and the relationships among them)?

Correlation matrix for data in 'expenditure' data set

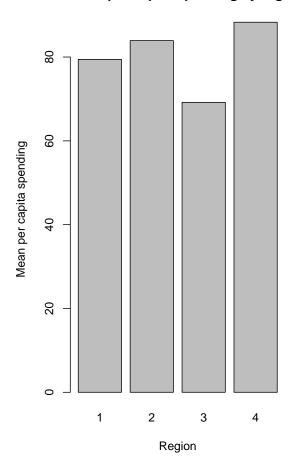

Y is moderately positively correlated to X1, with a correlation coefficient R=0.53, and is weakly positively correlated to X2 and X3, with R=0.45 and R=0.46 respectively. X1 is weakly positively correlated to X2 with R=0.21, and moderately correlated to X3 with R=0.6.

X2 and X3 are moderately positively correlated with R = 0.53.

The strongest correlation was seen between per capita income and numbers in urban residences.

• Please plot the relationship between Y and Region? On average, which region has the highest per capita expenditure on housing assistance?

Mean of per capita spending by region

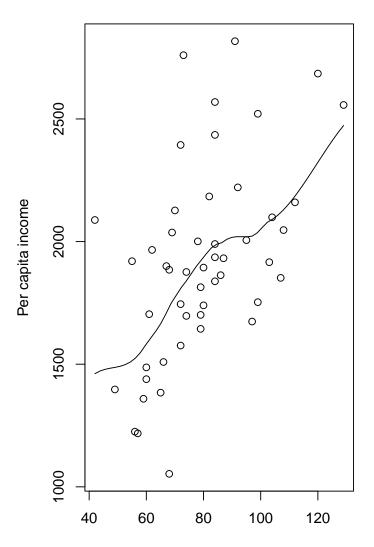

Region 4 has the highest mean per capital expenditure. This data was compiled by creating a dataframe of the means of Y, and the regions 1-4, using this code:

```
scatter.smooth(expenditure$X1, expenditure$X3, ylab="Urban (per thousand)
    ", xlab="Income per capita")
cor(expenditure$X1, expenditure$X3)
scatter.smooth(expenditure$X2, expenditure$X3)
cor(expenditure$Y, expenditure$X1)

Y_means_by_region <- aggregate(expenditure$Y, by = list(expenditure$Region), FUN = mean)</pre>
```

ullet Please plot the relationship between Y and X1? Describe this graph and the relationship.

Per capita expenditure on housing assistance

Y is moderately positively correlated to X1, with a correlation coefficient R = 0.53.

Reproduce the above graph including one more variable Region and display different regions with different types of symbols and colors.
